DESCRIPTION: The S30A40AC Series PWM servo amplifiers are designed to drive three phase brushless motors with sine wave current at a high switching frequency. They require two sinusoidal command signals with a 120-degree phase shift (external commutation). The phase angle must correspond to the position of the motor rotor, while the signal amplitude controls the motor torque. All models typically interface directly with digital controllers. The amplifiers are fully protected against over-voltage, under-voltage, over-current, over-heating, and short-circuits. The S30A40AC requires a single or three-phase AC power supply. A red/green LED and two digital outputs indicate operating status. All signal inputs and outputs are optically isolated from the power section to eliminate the need for a transformer coupled power supply.

SPECIFICATIONS:

All S30A40AC specifications are identical to the S30A40 specifications (see S30A40 series data sheets) except for:

These amplifiers contain a rectifier bridge and filter capacitors to generate the DC bus internally from the AC input power. The DC bus voltage is 1.4 times AC voltage (RMS), e.g. 310 VDC from 220 VAC. During braking much of the stored mechanical energy is fed back into the power supply and charges the bus capacitor to a higher voltage. If this voltage reaches the amplifier's over-voltage shutdown point, output current and braking will cease. To ensure smooth braking of large inertial loads, a built-in "shunt regulator" is provided in the S30A40AC. The shunt regulator will switch on the internal power resistor when the bus voltage reaches 390 VDC. This allows the bus capacitor to discharge and thus lower the bus voltage. During regeneration, the regeneration LED will blink (solid green is non-regeneration mode). An external shunt resistor can be added in parallel to the internal resistor (between C2-3 and C2-4). Recommended value is 20 ohms with a minimum 100 W rating. Removing the jumper between C2-4 and C2-5 will disable the internal shunt resistor. If the shunt regulator becomes inoperative the over voltage protection on the amplifier will disable the drive if the regeneration energy causes the bus voltage to exceed 420 VDC.

CURRENT LIMIT:

Current limiting for each motor winding is independent. The peak current is maintained for two seconds. If the RMS value of the winding current exceeds the RMS current limit the amplifier shuts off. The shut off condition is indicated by a high OVER CURRENT signal, a high FAULT signal, and a blinking red LED. The amplifier will re-enable when the RMS current returns to values within the RMS current limit range.

INPUT SIGNAL ISOLATION: All pins on P1/P3 are optically isolated (1000 V) from P2.
